

- A proposition is a sentence, written in a language, that has a truth value – it is true or false – in a world. A proposition is built from atomic propositions (atoms) and logical connectives.
- Propositions can be built from simpler propositions using logical connectives.

# Propositional Calculus Syntax

- An **atomic proposition** – **atom** – is a symbol, written as sequences of letters, digits, and the underscore (  $_$  ) and start with a lower-case letter.

E.g.,  $a$ ,  $ai\_is\_fun$ ,  $lit\_1$ ,  $live\_outside$ ,  $mimsy$ ,  $sunny$ .

- A **proposition** or **logical formula** is either
  - ▶ an atomic proposition or
  - ▶ a **compound proposition** of the form

$\neg p$	“not $p$ ”	<b>negation</b> of $p$
$p \wedge q$	“ $p$ and $q$ ”	<b>conjunction</b> of $p$ and $q$
$p \vee q$	“ $p$ or $q$ ”	<b>disjunction</b> of $p$ and $q$
$p \rightarrow q$	“ $p$ implies $q$ ”	<b>implication</b> of $q$ from $p$
$p \leftarrow q$	“ $p$ if $q$ ”	<b>implication</b> of $p$ from $q$
$p \leftrightarrow q$	“ $p$ if and only if $q$ ”	<b>equivalence</b> of $p$ and $q$
$p \oplus q$	“ $p$ XOR $q$ ”	<b>exclusive-or</b> of $p$ and $q$

where  $p$  and  $q$  are propositions.

- The operators  $\neg$ ,  $\wedge$ ,  $\vee$ ,  $\rightarrow$ ,  $\leftarrow$ ,  $\leftrightarrow$ , and  $\oplus$  are **logical connectives**.

# Why propositions?

- Logical formulae are modular statements of what is (known to be) true
- It is easier to check correctness and debug formulae than tables of what could be true
- We can exploit the Boolean nature for efficient reasoning
- We need a language for asking queries (of what follows in all models) that may be more complicated than asking for the value of a variable
- It is easy to incrementally add formulae
- It can be extended to infinitely many propositions with infinite domains (using logical quantification)

# Semantics of the Propositional Calculus

- An **interpretation** – or **possible world** – is an assignment of true or false to each variable.
- An interpretation is defined by function  $\pi$  that maps **atoms** to  $\{true, false\}$ .  
If  $\pi(a)=true$ , atom  $a$  is **true** in the interpretation.  
If  $\pi(a)=false$ , atom  $a$  is **false** in the interpretation.
- Truth of a compound proposition in an interpretation is defined in terms of the truth of its components:

$p$	$q$	$\neg p$	$p \wedge q$	$p \vee q$	$p \rightarrow q$	$p \leftarrow q$	$p \leftrightarrow q$	$p \oplus q$
<i>true</i>	<i>true</i>	<i>false</i>	<i>true</i>	<i>true</i>	<i>true</i>	<i>true</i>	<i>true</i>	<i>false</i>
<i>true</i>	<i>false</i>	<i>false</i>	<i>false</i>	<i>true</i>	<i>false</i>	<i>true</i>	<i>false</i>	<i>true</i>
<i>false</i>	<i>true</i>	<i>true</i>	<i>false</i>	<i>true</i>	<i>true</i>	<i>false</i>	<i>false</i>	<i>true</i>
<i>false</i>	<i>false</i>	<i>true</i>	<i>false</i>	<i>false</i>	<i>true</i>	<i>true</i>	<i>true</i>	<i>false</i>

- Propositions can have different truth values in different interpretations.

# Models and Logical Consequence

- A **model** of a set of clauses is an interpretation in which all the clauses are *true*.
- If  $KB$  is a set of propositions, proposition  $g$  is a **logical consequence** of  $KB$ , written  $KB \models g$ , if  $g$  is *true* in every model of  $KB$ .
- That is,  $KB \models g$  if there is no interpretation in which  $KB$  is *true* and  $g$  is *false*.

# Simple Example

$$KB = \begin{cases} \text{apple\_eaten} \leftarrow \text{bird\_eats\_apple.} \\ \text{light\_on} \leftarrow \text{night.} \\ \text{night.} \end{cases}$$

	<i>apple_eaten</i>	<i>bird_eats_apple</i>	<i>light_on</i>	<i>night</i>	model of <i>KB</i> ?
$I_1$	<i>true</i>	<i>true</i>	<i>true</i>	<i>true</i>	yes
$I_2$	<i>false</i>	<i>false</i>	<i>false</i>	<i>false</i>	no
$I_3$	<i>true</i>	<i>true</i>	<i>false</i>	<i>false</i>	no
$I_4$	<i>false</i>	<i>false</i>	<i>true</i>	<i>true</i>	yes
$I_5$	<i>true</i>	<i>false</i>	<i>true</i>	<i>true</i>	yes

Which of *apple\_eaten*, *bird\_eats\_apple*, *light\_on*, *night* logically follow from *KB*?

$KB \models \text{light\_on}$ ,  $KB \models \text{night}$ ,

$KB \not\models \text{apple\_eaten}$ ,  $KB \not\models \text{bird\_eats\_apple}$

# Human's view of semantics

**Step 1** Begin with a task domain.

**Step 2** Choose atoms in the computer to denote propositions. These atoms have meaning to the KB designer.

**Step 3** Tell the system knowledge about the domain.

**Step 4** Ask the system questions.

— The system can tell you whether the question is a logical consequence.

— You can interpret the answer with the meaning associated with the atoms.

# Computer's view of semantics

- The computer doesn't have access to the intended interpretation.
- All it knows is the knowledge base.
- The computer can determine if a formula is a logical consequence of KB.
- If  $KB \models g$  then  $g$  must be true in the intended interpretation.
- If  $KB \not\models g$  then there is a model of  $KB$  in which  $g$  is false. This could be the intended interpretation.

# Electrical Environment

## In computer:

$light2\_broken \leftarrow power\_in\_w\_3$   
 $\wedge sw\_3\_up \wedge unlit\_light2.$

$sw\_3\_up.$

$power\_in\_w\_3 \leftarrow power\_in\_p\_1.$

$unlit\_light2.$

$power\_in\_p\_1.$

## In user's mind:

- $light2\_broken$ : light #2 is broken
- $sw\_3\_up$ : switch 3 is up
- $power\_in\_w\_3$ : there is power in wire 3
- $unlit\_light2$ : light #2 isn't lit
- $power\_in\_p\_1$ : outlet  $p\_1$  has power

---

## Conclusion: $light2\_broken$

- The computer doesn't know the meaning of the symbols
- The user can interpret symbols using their meaning
